

DESCRIPTION OF THE DATASET

This dataset is a comprehensive collection of ATP tennis rankings, match results, and player statistics. The Kaggle link to the dataset is:

<https://www.kaggle.com/datasets/guillemservera/tennis>

This Kaggle page contains 3 datasets: The **matches** dataset, the **players** dataset and the **rankings** dataset, those 3 dataset offer a comprehensive information on tennis matches and player rankings.

It includes detailed records of matches, covering aspects such as player names, match dates, tournament details, and match outcomes. Additionally, the dataset provides player rankings, offering insights into the performance and standings of players over time. This extensive collection is valuable for analyzing **player performance trends**, **match statistics**, and the **evolution of player rankings** in the tennis world.

DATASET CREATION

The dataset created is a comprehensive **merge of three** distinct tennis-related tables, capturing details about tournaments, matches, and player rankings.

To create the final dataset have been used the following variables to execute the merge between the **matches** and the **players** dataset: "winner_id" from the matches table and "player_id" from the players table.

We have used those columns for the merge because both columns represent the same type of information: the player's unique identifier.

Therefore, using them for the merge ensures that the ranking information is added specifically for the player who won the match and for the players who lost the match against those winners.

Subsequently the merged dataset has been merged with the **ranking** tables using the columns "winner_id" and "tourney_date" from the previously merged dataset and the columns "player" and "ranking_date" from the ranking dataset.

We have used those columns because the tennis player rankings change over time, and the ranking dataset likely contains multiple entries for the same player on different dates.

If the merge were based only on "winner_id" and "player", it would introduce ambiguity because the ranking corresponding to the specific tournament date might not be selected.

Adding "tourney_date" and "ranking_date" ensures that the ranking data corresponds to the specific time period of the tournament.
